

The background is a solid teal color. Scattered across the frame are approximately 12 birds, likely pigeons, in various stages of flight. They are dark in color with lighter, possibly iridescent, wingtips. The birds are positioned at different heights and angles, creating a sense of movement and depth. The central text is white and stands out against the teal background.

Introduction to JAVA

History of Java

- Java was originally developed by Sun Microsystems starting in 1991
 - James Gosling
 - Patrick Naughton
 - Chris Warth
 - Ed Frank
 - Mike Sheridan
- This language was initially called **Oak**
- Renamed **Java** in 1995

What is Java?

- A simple, object-oriented, distributed, interpreted, robust, secure, architecture neutral, portable, high-performance, multithreaded, and dynamic language
---- Sun
- Object-Oriented
 - No free functions
 - All code belong to some class
 - Classes are in turn arranged in a hierarchy or package structure

What is Java?

- Distributed
 - Fully supports IPv4, with structures to support IPv6
 - Includes support for Applets: small programs embedded in HTML documents
- Interpreted
 - The program are compiled into Java Virtual Machine (JVM) code called bytecode
 - Each bytecode instruction is translated into machine code at the time of execution

What is Java?

- Robust
 - Java is simple – no pointers/stack concerns
 - Exception handling – try/catch/finally series allows for simplified error recovery
 - Strongly typed language – many errors caught during compilation

Java Development Environment

- Edit
 - Create/edit the source code
- Compile
 - Compile the source code
- Load
 - Load the compiled code
- Verify
 - Check against security restrictions
- Execute
 - Execute the compiled

Phase 1: Creating a Program

- Any text editor or Java IDE (Integrated Development Environment) can be used to develop Java programs
- Java source--code file names must end with the **.java** extension
- Some popular Java IDEs are
 - NetBeans
 - Eclipse
 - JCreator
 - IntelliJ

Phase 2: Compiling a Java Program

- ***javac Welcome.java***
 - Searches the file in the current directory
 - Compiles the source file
 - Transforms the Java source code into bytecodes
 - Places the bytecodes in a file named **Welcome.class**

Bytecodes

- They are not machine language binary code
- They are independent of any particular microprocessor or hardware platform
- They are platform--independent instructions
- Another entity (interpreter) is required to convert the bytecodes into machine codes that the underlying microprocessor understands
- This is the job of the **JVM** (Java Virtual Machine)

JVM (Java Virtual Machine)

- It is a part of the JDK and the foundation of the Java platform
- It can be installed separately or with JDK
- A virtual machine (VM) is a software application that simulates a computer, but hides the underlying operating system and hardware from the programs that interact with the VM
- It is the JVM that makes Java a portable language

JVM (Java Virtual Machine)

- The same bytecodes can be executed on any platform containing a compatible JVM
- The JVM is invoked by the java command
 - ***java Welcome***
- It searches the class Welcome in the current directory and executes the main method of class Welcome
- It issues an error if it cannot find the class Welcome or if class Welcome does not contain a method called main with proper signature

Phase 3: Loading a Program

- One of the components of the JVM is the class loader
- The class loader takes the .class files containing the programs bytecodes and transfers them to RAM
- The class loader also loads any of the .class files provided by Java that our program uses

Phase 4: Bytecode Verification

- Another component of the JVM is the bytecode verifier
- Its job is to ensure that bytecodes are valid and do not violate Java's security restrictions
- This feature helps to prevent Java programs arriving over the network from damaging our system

Phase 5: Execution

- Now the actual execution of the program begins
- Bytecodes are converted to machine language suitable for the underlying OS and hardware
- Java programs actually go through two compilation phases
 - Source code --> Bytecodes
 - Bytecodes --> Machine language

Editing a Java Program

```
1  /**
2   * Created by rifat on 20/08/15.
3   */
4  public class Welcome {
5      public static void main(String[] args) {
6          System.out.println("Hello Java");
7          System.out.printf("I like %s\n", "Java");
8          String strDepartment = "CSE";
9          System.out.print("We study in " + strDepartment + "\n");
10     } // end method main
11 } // end class Welcome - NOTE: no semicolon is required here
12
```

Examining Welcome.java

- A Java source file can contain multiple classes, but only one class can be a public class
- Typically Java classes are grouped into packages (similar to namespaces in C++)
- A public class is accessible across packages
- The source file name must match the name of the public class defined in the file with the .java extension

Examining Welcome.java

- In Java, there is no provision to declare a class, and then define the member functions outside the class
- Body of every member function of a class (called method in Java) must be written when the method is declared
- Java methods can be written in any order in the source file
- A method defined earlier in the source file can call a method defined later

Examining Welcome.java

- ***public static void main(String[] args)***
 - **main** is the starting point of every Java application
 - **public** is used to make the method accessible by all
 - **static** is used to make main a static method of class Welcome. Static methods can be called without using any object; just using the class name. JVM call main using the **ClassName.methodName** notation
 - **void** means main does not return anything
 - **String args[]** represents an array of String objects that holds the command line arguments passed to the application. *Where is the length of args array?*

Examining Welcome.java

- Think of JVM as a outside Java entity who tries to access the main method of class Welcome
 - main must be declared as a public member of class Welcome
- JVM wants to access main without creating an object of class Welcome
 - main must be declared as static
- JVM wants to pass an array of String objects containing the command line arguments
 - main must take an array of String as parameter

Examining Welcome.java

- ***System.out.println()***
 - Used to print a line of text followed by a new line
 - **System** is a class inside the Java API
 - **out** is a public static member of class System
 - **out** is an object of another class of the Java API
 - **out** represents the standard output (similar to stdout or cout)
 - **println** is a public method of the class of which out is an object

Examining Welcome.java

- **System.out.print()** is similar to **System.out.println()**, but does not print a new line automatically
- **System.out.prinC()** is used to print formatted output like printf() in C
- In Java, characters enclosed by double quotes (" ") represents a String object, where String is a class of the Java API
- We can use the plus operator (+) to concatenate multiple String objects and create a new String object

Compiling a Java Program

- Place the .java file in the bin directory of your Java installation
 - ***C:\Program Files\Java\jdk1.8.0_51\bin***
- Open a command prompt window and go to the bin directory
- Execute the following command
 - ***javac Welcome.java***
- If the source code is ok, then javac (the Java compiler) will produce a file called Welcome.class in the current directory

Compiling a Java Program

- If the source file contains multiple classes then javac will produce separate .class files for each class
- Every compiled class in Java will have their own .class file
- .class files contain the bytecodes of each class
- So, a .class file in Java contains the bytecodes of a single class only

Executing a Java Program

- After successful compilation execute the following command
 - ***java Welcome***
 - *Note that we have omitted the .class extension here*
- The JVM will look for the class file *Welcome.class* and search for a *public static void main(String args[])* method inside the class
- If the JVM finds the above two, it will execute the body of the main method, otherwise it will generate an error and will exit immediately

Another Java Program

```
A.java x
1  /**
2   * Created by rifat on 21/08/15.
3   */
4  public class A {
5      private int a;
6
7      public A()
8      {
9          this.a = 0;
10     }
11
12     public void setA(int a)
13     {
14         this.a = a;
15     }
16
17     public int getA()
18     {
19         return this.a;
20     }
21 }
```

```
21
22
23
24     public static void main(String args[])
25     {
26         A ob;
27         ob=new A();
28         ob.setA(10);
29         System.out.println(ob.getA());
30     }
```

Examining A.java

- The variable of a class type is called a reference
 - *ob* is a reference to A object
- Declaring a class reference is not enough, we have to use new to create an object
- Every Java object has to be instantiated using keyword **new**
- We access a public member of a class using the dot operator (.)
 - Dot (.) is the only member access operator in Java.
 - Java does not have ::, -->, & and *
